S1 Pre-experiment survey

Before implementing our main survey experiment in April 2016, we conducted a pre-experiment survey in January 2016 to collect basic information about the respondents' knowledge of fracking; their familiarity with technical, economic, and environmental arguments about fracking; their views on the political salience of fracking; and their support for fracking. The sample size was $n = 1,704$.

Here, we enumerate the questions that were asked in the pre-treatment survey and the response categories that were available for each question. A "don't know" or "not sure" option was always given as an additional response option.

1. *Have you ever heard about fracking?* Response categories: Yes (= 1); No (= 0).
2. *How familiar are you with the technical details of hydraulic fracturing?* Response categories: 1 – 6 scale, ranging from "very unfamiliar" (= 1) to "very familiar" (= 6).
3. *How familiar are you with the economic arguments in favor of hydraulic fracturing?* Response categories: 1 – 6 scale, ranging from "very unfamiliar" (= 1) to "very familiar" (= 6).
4. *How familiar are you with the environmental arguments against hydraulic fracturing?* Response categories: 1 – 6 scale, ranging from "very unfamiliar" (= 1) to "very familiar" (= 6).
5. *How important is fracking as a political issue?* Response categories: 1 – 3 scale, ranging from "very important" (= 1) to "not important" (= 3).
6. *On balance, do you favor or oppose fracking?* Response categories: 1 – 6 scale, ranging from "strongly oppose" (= 1) to "strongly favor" (= 6).
7. *Based on your knowledge, what do you believe is the strongest argument in favor of fracking?*
Response category: Open ended text entry.
8. *Based on your knowledge, what do you believe is the strongest argument against fracking?*
Response category: Open ended text entry.

S2 Summary statistics from pre-experiment survey

We report summary statistics for our pre-experiment survey here. The first two tables [S1](#) and [S2](#) provide basic summary statistics from the full-sample data, both without and with survey weights. The next two tables show the estimated means of the main variables, separately for states with and without fracking at the respondent level (Table [S3](#)) and state level (Table [S4](#)), together with p-values from Wald tests for whether means across groups are equal. The means were estimated using sampling and post-stratification weights. We do not find a systematic difference among respondents based on whether there was fracking activity in their state of residence.

	<i>n</i>	Mean	SD	Min	Max
Fracking support (January)	1137	3.22	1.49	1	6
Heard about fracking	1629	0.83	0.37	0	1
Technical knowledge about fracking	1539	3.09	1.43	1	6
Economic knowledge about fracking	1529	3.37	1.46	1	6
Environmental knowledge about fracking	1539	3.61	1.49	1	6
Political salience of fracking	1207	2.11	0.68	1	3

Table S1: Sample summary statistics from the pre-experiment survey.

	<i>n</i>	Mean	SD	Min	Max
Fracking support (January)	1137	3.15	1.44	1	6
Heard about fracking	1629	0.77	0.41	0	1
Technical knowledge about fracking	1539	2.83	1.40	1	6
Economic knowledge about fracking	1529	3.10	1.46	1	6
Environmental knowledge about fracking	1539	3.38	1.53	1	6
Political salience of fracking	1207	2.05	0.66	1	3

Table S2: Summary statistics from the pre-experiment survey with survey weights.

	n	Group means for U.S. states		p-value
		Non-fracking	Fracking	
Fracking support (January)	1137	3.18	3.12	0.686
Heard about fracking	1629	0.75	0.80	0.131
Technical knowledge about fracking	1539	2.81	2.86	0.680
Economic knowledge about fracking	1529	3.03	3.18	0.245
Environmental knowledge about fracking	1539	3.31	3.47	0.226
Political salience of fracking	1207	2.09	1.99	0.099

Table S3: Mean comparison at respondent level by whether the state has fracking activity. Means are adjusted by survey weights. The last column reports p-values from an adjusted Wald test.

	n	Group means for U.S. states		p-value
		Non-fracking	Fracking	
Fracking support (January)	51	3.27	3.35	0.603
Heard about fracking	51	0.83	0.88	0.194
Technical knowledge about fracking	51	3.21	3.25	0.460
Economic knowledge about fracking	51	3.36	3.44	0.680
Environmental knowledge about fracking	51	3.55	3.74	0.186
Political salience of fracking	51	2.03	2.00	0.702

Table S4: Mean comparison at state level by whether the state has fracking activity. Means are adjusted by survey weights. The last column reports p-values from an adjusted Wald test.

S3 Responses from Amazon Mechanical Turk pre-test

Prior to fielding our pre-treatment survey and main survey experiment, we collected a convenience sample of $n = 187$ respondents on Amazon’s Mechanical Turk (MTurk) from two surveys in September 2015 and December 2015. The frames we presented to respondents reflected the main arguments in the public debate on fracking in the United States at the time. Specifically, our frames against fracking focused on (i) water contamination; (ii) the uncertain consequences of fracking, including earthquakes; (iii) a diversion of investment away from renewables (only asked in the December survey); and (iv) risks to private lands. Our frames in support of fracking focused on (i) job creation, (ii) energy security, (iii) tax revenues, and (iv) lower oil and gasoline prices.

For each frame, we asked respondents whether that frame opposes or supports fracking and the strength of that frame in swaying their opinion. Since we used the same wording for each treatment text in this MTurk pre-test as in the main experiment, this exercise helps us validate our experimental survey instrument.

Frame	n	Directionality (mean)	Strength (mean)	Top rank (percent)
<i>Anti-fracking frames</i>				
Water	186	1.69	4.84	76%
Uncertainty	187	2.03	4.02	61%
Diversion from clean energy	86	2.09	4.24	10%
Land use	186	2.18	3.63	44%
<i>Pro-fracking frames</i>				
Jobs	186	5.43	4.29	36%
Energy security	184	5.39	4.09	29%
Tax revenue	186	5.18	3.87	21%
Energy prices	186	5.25	4.07	27%

Table S5: Pre-test from MTurk sample ($n = 187$). For each frame, we report the number of responses (column 2), whether respondents believe the frame opposes fracking (low values) or favors fracking (high values) on a 1 – 6 scale (column 3), how weak (low values) or strong (high values) on a 1 – 6 scale a frame is (column 4), and how often (in %) a frame is considered among the top three most persuasive arguments (column 5). In the “directionality” column, values closer to 6 suggest support for fracking and values closer to 1 suggest opposition towards fracking. In the “strength” column, values closer to 6 suggest a stronger frame and values closer to 1 suggest a weaker frame.

The table above reports how respondents in the pre-test scored the directionality and strength of each frame. On a scale from 1 – 6, low/high values indicate opposition to/support for fracking (labeled as directionality) and denote the weakness or strength of each argument (labeled as strength), independent of its direction. We also had respondents rank all eight frames based on their persuasiveness.

It is apparent that the benefits of fracking are usually framed with reference to jobs created and to energy security. Moreover, the risks and costs of fracking are presented with reference to water contamination and uncertain environmental consequences. While the diversion argument does not rank as highly among respondents, it is relevant for the long-term transition toward a low carbon economy.

S4 Ordering effects

The treatment conditions involving counter-frames combine supporting and opposing arguments about fracking. To rule out ordering effects from showing some arguments always before others, we randomized the order in which frames are shown. For example, for the condition that was assigned to receive both the water contamination and job creation frame, half of the respondents saw the water argument followed by the job creation frame, while the other half saw the job creation frame before the water contamination frame.

Table S6 below shows the results from comparing the means of fracking support by frame order. The final two columns report p-values from two tests: a simple, two-sided t-test of means and a χ^2 test of whether the entire distribution of the 6-point fracking support variable differs systematically by frame order. We highlight statistical significance in bold and find only a single test for which the test statistic falls below the 5% significance threshold. This makes us confident to rule out the possibility of ordering effects.

#	Condition	<i>n</i>	Means		p-values	
			Group 1	Group 2	t-test	χ^2 test
7	Water + Jobs	117	3.21	2.92	0.268	0.841
8	Water + Energy security	123	2.69	2.49	0.435	0.743
9	Uncertainty + Jobs	124	2.95	3.26	0.277	0.132
10	Uncertainty + Energy security	121	2.80	3.35	0.033	0.384
11	Diversion + Jobs	139	3.07	3.26	0.487	0.575
12	Diversion + Energy security	118	2.96	2.80	0.556	0.057

Table S6: Fracking support, by frame order, for counterframe treatment conditions.

S5 Main results

This section reports our main results. Below, we show means and p-values from comparing each frame against the control group mean. We report means and significance levels without and with survey weights. We indicate statistically significant results below the 5% significance level in bold.

#	Condition	Without survey weights		With survey weights	
		Mean	p-value	Mean	p-value
1	Control	3.32	—	3.39	—
2	Water	2.42	0.000	2.39	0.000
3	Uncertainty	2.68	0.001	2.66	0.029
4	Diversion	2.77	0.012	2.65	0.029
5	Jobs	3.78	0.034	3.58	0.588
6	Energy security	3.75	0.044	3.73	0.326
7	Water + Jobs	3.07	0.212	3.39	0.981
8	Water + Energy security	2.60	0.000	2.57	0.010
9	Uncertainty + Jobs	3.09	0.270	2.90	0.102
10	Uncertainty + Energy security	3.07	0.206	2.91	0.124
11	Diversion + Jobs	3.16	0.427	2.98	0.197
12	Diversion + Energy security	2.88	0.037	2.76	0.046

Table S7: Main results for single frames and counterframes. For each frame/condition, we report means and p-values from comparing the mean against the control group mean. Values closer to 1 indicate opposition to fracking and values closer to 6 indicate support for fracking. Columns (2) and (3) report results without survey weights and columns (4)-(5) show results when survey weights are applied. We highlight statistical significance below the 5% threshold in bold.

S6 Multiple comparisons

Our study design has twelve experimental conditions. As we compare group means of each condition against the control group means, we end up with eleven comparisons; correcting p-values is advisable.

Table S8 shows corrected p-values from three popular correction methods: the Bonferroni, Bonferroni-Holm, and Benjamini-Hochberg corrections. As it is *a priori* unclear what the ‘correct’ correction method is, we prefer to report results from multiple ones, especially as the Bonferroni-based methods correct for the family-wise error rate, while the Benjamini-Hochberg correction corrects for the false discovery rate. The latter is often considered more lenient.

We only report multiple comparison corrections for results which are significant before the correction. We highlight statistical significance again in bold and show that levels of statistical significance do not change too much even when correcting for multiple comparisons.

#	Condition	p-value	Type of p-value correction		
			Bonferroni	Bonferroni-Holm	Benjamini-Hochberg
1	Control	—	—	—	—
2	Water	0.000	0.000	0.000	0.000
3	Uncertainty	0.001	0.011	0.009	0.003
4	Diversion	0.012	0.132	0.096	0.033
5	Jobs	0.034	0.374	0.238	0.067
6	Energy security	0.044	0.484	0.238	0.069
7	Water + Jobs	0.212	—	—	—
8	Water + Energy security	0.000	0.000	0.000	0.000
9	Uncertainty + Jobs	0.270	—	—	—
10	Uncertainty + Energy security	0.206	—	—	—
11	Diversion + Jobs	0.427	—	—	—
12	Diversion + Energy security	0.037	0.407	0.238	0.067

Table S8: Multiple comparison p-value corrections. Column (3) shows the original p-values we report in the main text. Columns (4)-(6) report corrected p-values using the Bonferroni, Bonferroni-Holm, and Benjamini-Hochberg methods. Statistical significance at 5% level is indicated in bold.

S7 Interaction models: Fracking knowledge

In this section we show results from statistical tests of heterogeneous treatment effects. In particular, we are interested in whether fracking knowledge may condition our main results. For this, we use respondent information from our pre-experiment survey, conducted in January 2016, to ensure that these variables are truly measured pre-treatment.

We carry out two distinct tests: First, we use respondent information on self-reported fracking knowledge as a conditioning variable to proxy for information levels about fracking. Second, we use non-response or “Don’t know” information from the pre-experiment survey to construct a measure for lacking information. We discuss and present results from these two tests in turn.

Test 1: Conditioning effect of high knowledge

The first conditioning variable we use comes from three questions about fracking knowledge from the pre-experiment survey. Specifically, we asked respondents about their familiarity with the technical details of fracking as well as their familiarity with environmental and economic arguments on the issue. Respondents could answer on a 1–6 scale, ranging from “very unfamiliar” to “very familiar.” We aggregate information from these three survey questions into a new variable of overall fracking knowledge. A respondent is coded as having “high knowledge” if they reported familiarity scores of at least 5 in all three familiarity questions; “low knowledge” respondents are those with scores of less than 2 throughout; all others fall in a medium category.

To facilitate the direct interpretation of the interaction effects, we recode our conditioning variables into binary variables to contrast treatment effects for those with high knowledge against those with medium or low levels.

We also show a more complete interaction model that includes various other control variables: whether a respondent has already formed an opinion on fracking (3 levels); a respondent’s assessment of their economic situation (5 levels); a respondent’s view towards global warming (4 levels); a respondent’s age (continuous) and gender (2 levels); whether the respondent identifies as Republican (binary) or Democrat (binary); a respondent’s household income (6 levels); how politically interested the respondent is (4 levels); and whether the respondent lives in a state with fracking

activity (binary), coded as a US state with shale oil or gas production in 2016, according to U.S. Energy Information Administration data. All models include state fixed effects and robust standard errors.

In general, we find virtually no evidence of any statistically significant interaction effects, let alone any systematic effects. This is the case when we use the above described index variable of knowledge across technical, economic, and environmental dimensions of fracking as well as when we use self-reported knowledge on these dimensions separately.

Table S12: Regression results from interaction models when environmental fracking knowledge is the conditioning variable. Negative values indicate a reduction in support for fracking and positive values indicate an increase in support for fracking.

Test 2: Conditioning effect of no knowledge

As an alternative test of how information may condition the main experimental results, we use evidence for the lack of knowledge. Among the respondents in our main experiment, only 237 (out of 1525, 15.5%) reported not having heard of fracking, so the topic *per se* was well known among most respondents. Having heard of fracking, as we show in the discussion of our pre-experiment survey, does not translate into robust knowledge of the topic.

We, therefore, constructed a more useful measure. To do so, we used information from the pre-experiment survey's open-ended responses. We asked respondents to name what they think represents the strongest argument in favor of or against fracking. We then coded each respondent who did not provide an answer to both of these questions as having "low prior knowledge" on fracking. This leaves us with a higher share of more than a quarter of respondents with little-to-no fracking knowledge. This binary variable serves as a conditioning variable in the same model specifications as reported above.

We do not find any systematic effects of lacking prior knowledge of a specific argument about fracking. Hence, there is no evidence that respondents with no prior knowledge are more responsive to our treatment effects.

S8 Interaction models: Congruent information

Our fourth hypothesis expects that *congruent* information conditions the effectiveness of frames and counter-frames. For this, we again relied on information provided by responses to open-ended questions in the pre-experiment survey. We simply assessed whether the effectiveness of frames and counter-frames that, for instance, involve the water frame increased among respondents who mentioned water contamination as the strongest argument against fracking in the pre-experiment survey.

This is what we refer to as congruent information. Since only six respondents named the diversion argument in the open-ended responses, we cannot run interaction models with those respondents included, but we can for all other four main frames. We kept all other specifications exactly the same as above, i.e., we included the same set of covariates and include state fixed effects.

From these additional models, we found that congruent information can condition the effectiveness of framing effects, at least for the water frame. We found that respondents who mentioned water contamination from fracking in their open-ended responses do show less support for fracking when they are presented with a water frame. Interestingly, these respondents also showed less favorable attitudes toward fracking across many other frames as well. This could suggest that when respondents who already hold concerns against fracking are presented with additional anti-fracking arguments (either as single frames or counter-frames), this amplifies their opposition against fracking. Here, information would be congruent in terms of offering additional anti-fracking arguments rather than exactly the same argument.

This effect is only present for the water frame pre-treatment information, but no such effects occur with any of the other pre-treatment arguments, either the anti-fracking or pro-fracking ones.

Fracking state					2.116***	0.706
Observations	716		535		405	

Dependent Variable: Fracking support (1-6 scale). Higher values indicate more support for fracking.

All models with state fixed effects and robust standard errors.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table S16: Regression results from interaction models when pre-treatment open-ended responses mentioning job creation is the conditioning variable. Negative values indicate a reduction in support for fracking and positive values indicate an increase in support for fracking.
